AUGMENTING/MODIFYING THE DATA

- Adding noise expands the size of the training dataset. Each time a training sample is exposed to the model, random noise is added to the input variables making them different every time it is exposed to the model.
- This is done to overcome a common problem known as Overfitting when a model learns the detail and noise in the training data to the extent that it negatively impacts the performance of the model on new data.
- When you train a neural network with small datasets, the network generally memorizes the training dataset instead of learning general features of our data. For this reason, the model will perform well on the training set and poor on new data, hence, this technique is applied.
